1

- So far we have worked with single numerical and categorical variables, and explored relationships between numerical and categorical, and two categorical variables.

- In this unit we will learn to quantify the relationship between two numerical variables, as well as modeling numerical response variables using a numerical or categorical explanatory variable.

- In the next unit we'll learn to model numerical variables using many explanatory variables at once.

Clicker question

Which of the following is the best guess for the correlation between annual murders per million and percentage living in poverty?
(a) -1.52

(b) -0.63

(c) -0.12

(d) 0.02

(e) 0.84

3

Clicker question

Which of the following is the best guess for the correlation between annual murders per million and population size?

(a) -0.97

(b) -0.61

(c) -0.06

(d) 0.55

(e) 0.97

Clicker question

Which of the following is has the strongest correlation, i.e. correlation coefficient closest to +1 or -1?

Upload a screen shot to Sakai (EC - Correlation Game) by midnight on Nov 20 (along with PS 6) for extra credit (1 pt on the problem set).
http://mih5.github.io/correlation_game2/correlationgame.html

Remember: correlation does not always imply causation!
http://www.tylervigen.com/

- ▶ Residuals are the leftovers from the model fit, and calculated as the difference between the observed and predicted y: $e_i = y_i - \hat{y}_i$
- ▶ The least squares line minimizes squared residuals:
  - – Population data: $\hat{y} = \beta_0 + \beta_1 x$
  - – Sample data: $\hat{y} = b_0 + b_1 x$
- ▶ *Slope:* For each <u>unit</u> increase in <u>x</u>, <u>y</u> is expected to be<u>higher/lower</u> on average by <u>the slope</u>.

$$b_1 = \frac{s_y}{s_x} R$$

- ▶ *Intercept:* When <u>$x = 0$</u>, <u>y</u> is expected to equal <u>the intercept</u>.
$$b_0 = \bar{y} - b_1 \bar{x}$$

  - – The calculation of the intercept uses the fact the a regression line **always** passes through $(\bar{x}, \bar{y})$.

Why does the regression line **always** pass through $(\bar{x}, \bar{y})$?

- ▶ If there is no relationship between x and y ($b_1 = 0$), the best guess for $\hat{y}$ for any value of x is $\bar{y}$.
- ▶ Even when there is a relationship between x and y ($b_1 \neq 0$), the best guess for $\hat{y}$ when $x = \bar{x}$ is still $\bar{y}$.

Application exercise: 6.1 Linear model

See course website for details

What is the interpretation of the slope?

(a) Each additional percentage in those living in poverty increases number of annual murders per million by 2.56.

(b) For each percentage increase in those living in poverty, the number of annual murders per million is expected to be higher by 2.56 on average.

(c) For each percentage increase in those living in poverty, the number of annual murders per million is expected to be lower by 29.91 on average.

(d) For each percentage increase annual murders per million, the percentage of those living in poverty is expected to be higher by 2.56 on average.
Suppose you want to predict annual murder count (per million) for a series of districts that were not included in the dataset. For which of the following districts would you be most comfortable with your prediction?
A district where % in poverty =

(a) 5%

(b) 15%

(c) 20%

(d) 26%

(e) 40%

A note about the intercept

Sometimes the intercept might be an extrapolation: useful for adjusting the height of the line, but meaningless in the context of the data.

Summary of main ideas

1. Correlation coefficient describes the strength and direction of the linear association between two numerical variables

2. Least squares line minimizes squared residuals

3. Interpreting the least squares line

4. Predict, but don't extrapolate
